

TCP/UDP Basics

Transport Service Overview

- Provide service to application layer by using the service provided by network layer
- Hide physical network
 - Hide processing complexity
 - Hide different network technologies and architectures
- Provide reliable, host-to-host transport

Transport layer design issues

- Addressing
- Connection Establishment
- Connection Release
- Flow Control
- Error Detection and Crash Recovery

Agenda

- TCP: Transmission control protocol (RFC 793)
 - Addressing
 - Connection Establishment
 - Connection Release
 - Flow Control
 - Error Handling
 - Interface and State Machine
 - TCP application examples
- UDP: User datagram protocol (RFC 768)
- TCP vs. UDP

TCP -- Addressing

- There are many network applications running on a host. When a packet arrive at network layer, how to know which application to send to?
 - Port: there are $2^{16} = 65536$ ports (0-65535) on one machine
 - One port is linked to only one application
 - One application may use many ports for different purposes
 - e.g. FTP: 20, 21
- How a client knows which service uses which port?
 - Permanent, well-known: often used service
 - 0-1023: well-known ports
 - 1024-49151: registered ports
 - 49152-65535: private ports
 - Process server proxy and create service on-the-fly: temporary service
 - Name server: for file service

TCP Addressing Header Fields

TCP Connection Establishment – design issue

- Connection establishment becomes tricky when the network lose, delay and duplicate packets
 - Bank example
- How to differentiate a new packet from a delayed, duplicated packet
 - Sequence number
 - Sequence number increase for each packet
 - Sequence number space issue:
 - Sequence number wrap back
 - A packet should avoid using a sequence number that another packet is using
 - A duplicated or delayed packet should die after a while
 - IP layer already handles this issue by 'Time To Live' header field

TCP Connection Related Header Fields

TCP Connection Establishment – solution three way handshake

(a) TCP connection establishment in the normal case.

(b) Call collision.

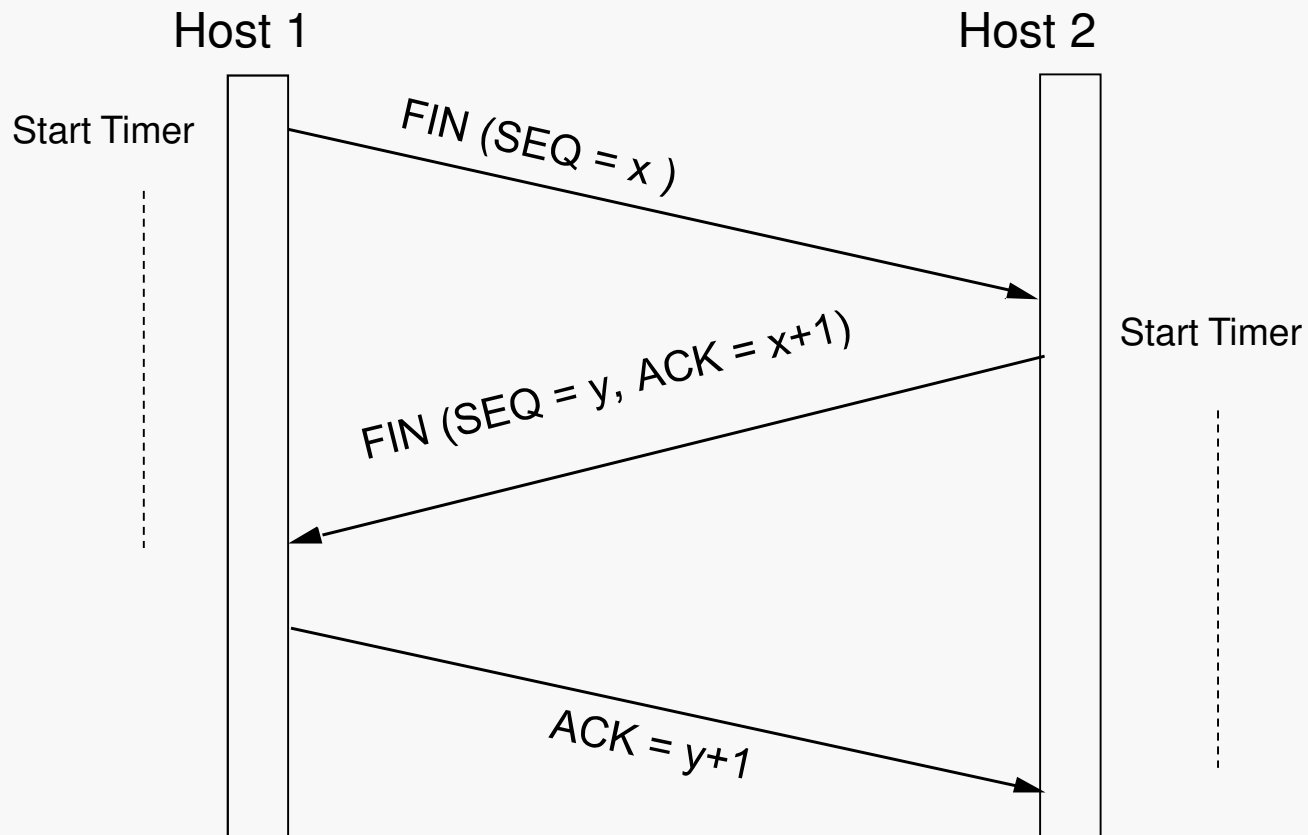

TCP Connection Release – design options and issue (1)

- Two release methods: asymmetric and symmetric
- Asymmetric release issue: possibility of losing data

TCP Connection Release – solution

Three way handshake + timeout

TCP Flow Control – design issue

- Speed of data sending is critical

- Too fast:

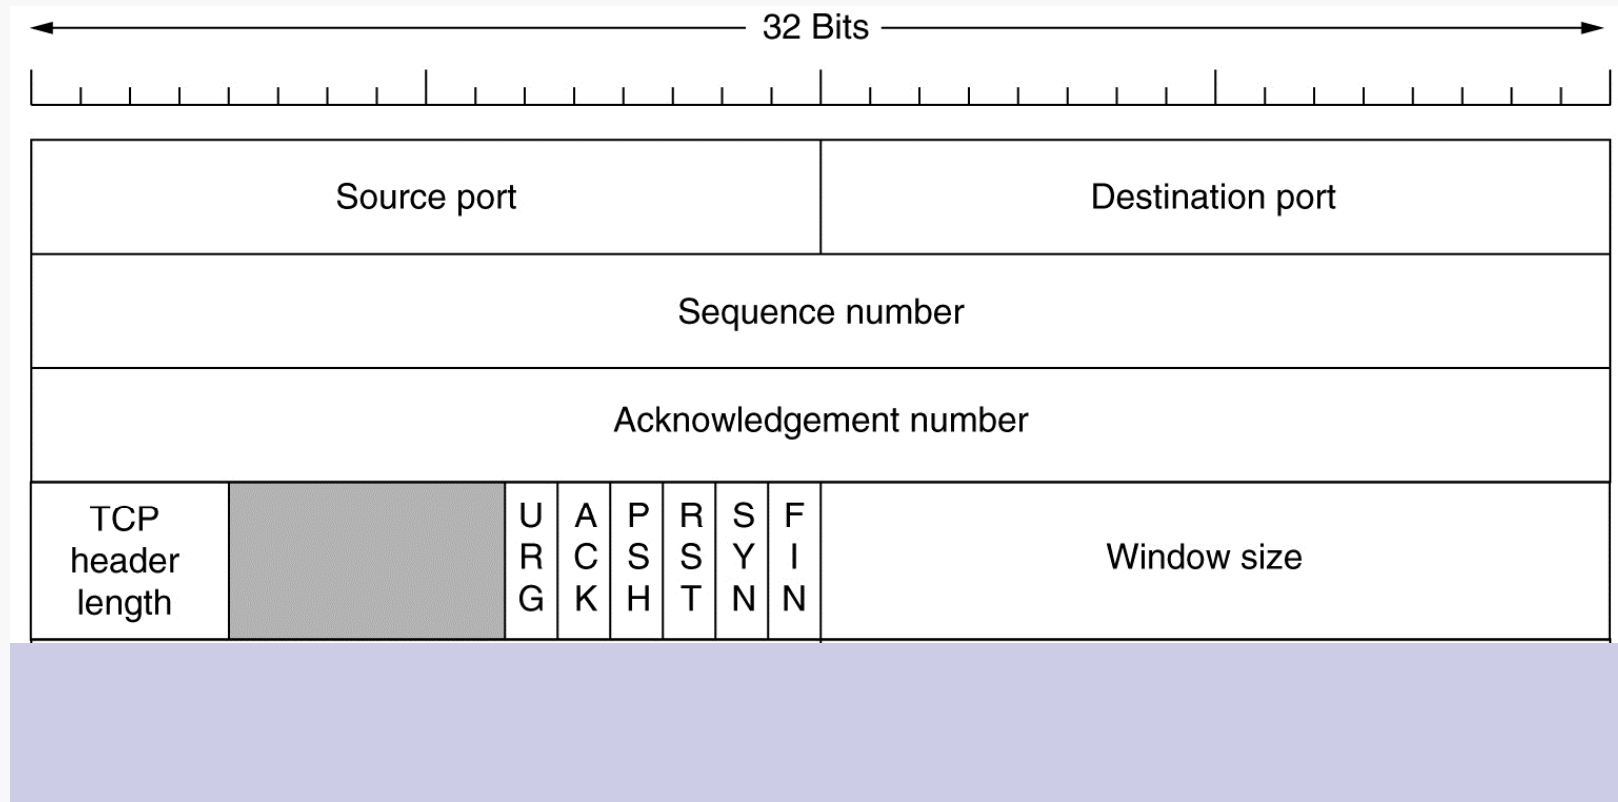

- network congestion or
- receiving side overload

- Too slow – type example

- waste of network resource or receiving memory

TCP Flow Control – solution (1)

- Windows maintained by both sending and receiving hosts
- Receiving side window size is decided by the available capability of receiving host's
- Sender maintains two windows
 - receiver window (got from receiving host), congestion window (to calculate)

TCP Flow Control – congestion window size calculation

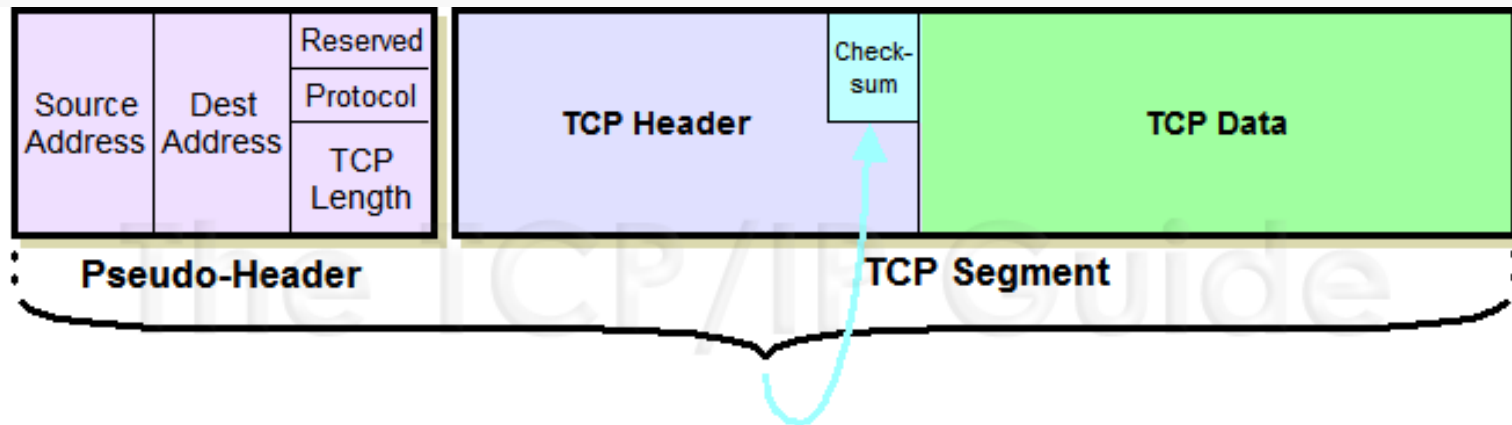

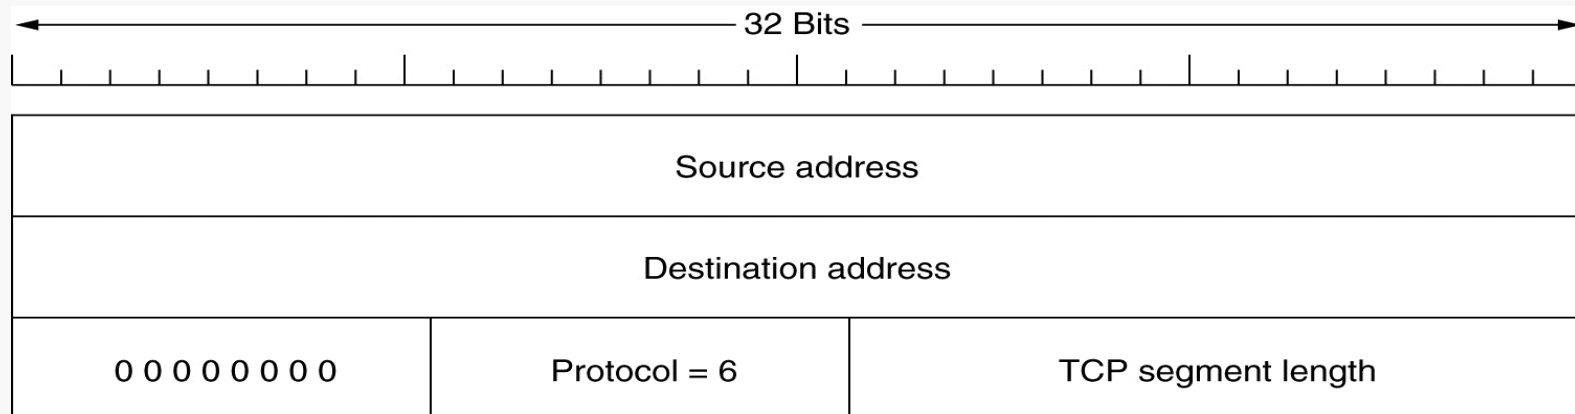

- slow start, reaching threshold, linear increment till timeout, recalculate threshold, slow start... till reaching receiver window size or timeout...

TCP Error Handling

- Host crash and recovery
- Data error during transmission

TCP Error Handling – TCP checksum

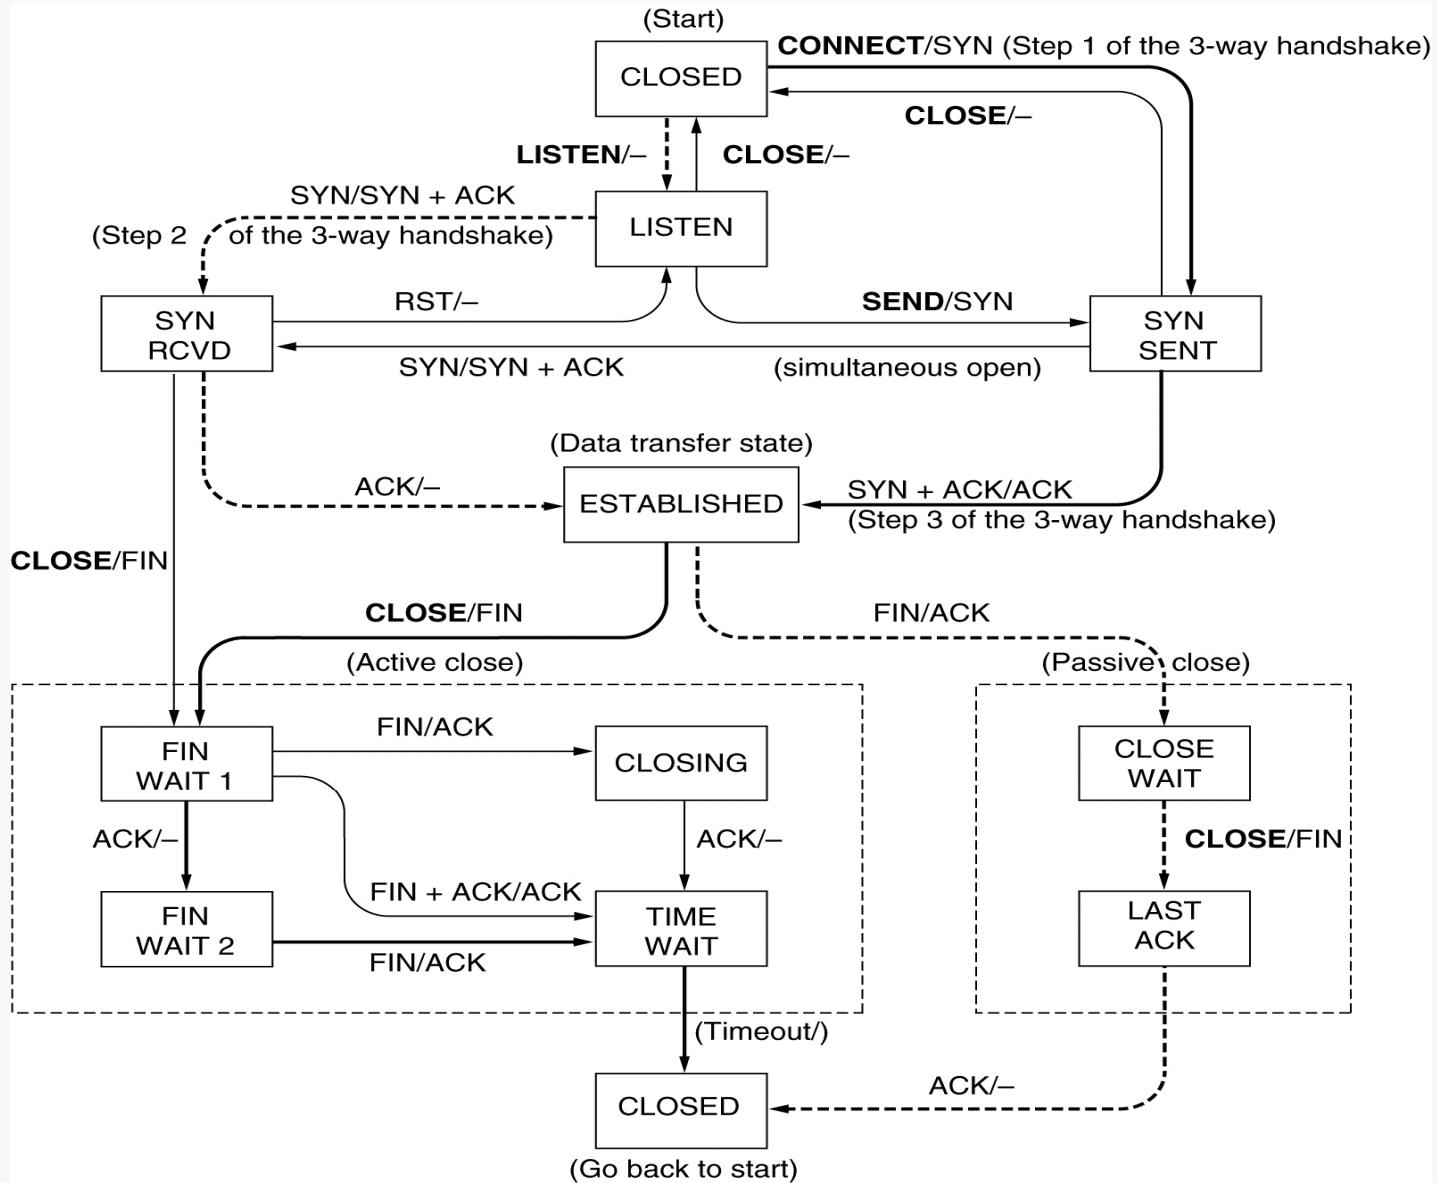

Checksum Calculated Over Pseudo Header and TCP Segment

TCP service primitives

Primitive	Meaning
SOCKET	Create a new communication end point
BIND	Attach a local address to a socket
LISTEN	Announce willingness to accept connections; give queue size
ACCEPT	Block the caller until a connection attempt arrives
CONNECT	Actively attempt to establish a connection
SEND	Send some data over the connection
RECEIVE	Receive some data from the connection
CLOSE	Release the connection

TCP Finite State Machine

TCP application examples

■ When to use TCP:

- When an application need a reliable transport

■ Examples

- File Transfer Protocol : FTP (21)
- Secure Shell: SSH (22)
- Teletype Network: TELNET (23)
- Simple Mail Transfer Protocol: SMTP (25)
- Hypertext Transfer Protocol: HTTP (80)

Agenda

- TCP: Transmission control protocol (RFC 793)
- UDP: User datagram protocol (RFC 768)
 - UDP header
 - UDP properties
 - UDP application examples
- TCP vs. UDP

UDP Header

- UDP Destination Port: identifies destination process
- UDP Source Port: optional – identifies source process for replies, or zero
- Message Length: length of datagram in bytes, including header and data
- Checksum: optional -- 16-bit checksum over header and data, or zero

UDP Properties

- UDP provides an unreliable datagram service
 - Packets may be lost or delivered out of order
 - Message split into datagrams, user sends datagrams as packets on network layer
 - No buffer at either sending or receiving side
 - Unreliable but fast
 - Full duplex
 - Application must deal with lost packets

UDP Application Examples

■ When to use UDP

- Reduce the requirement of computer resources
- The checking scheme has provided completely by the application program
- When using the Multicast or Broadcast to transfer
- The transmission of Real-time packets

■ Examples

- Trivial File Transfer Protocol , TFTP
- Simple Network Management Protocol , SNMP
- Dynamic Host Configuration Protocol , DHCP
- Domain Name System , DNS
- Routing Information Protocol , RIP
- Real-Time Transport Protocol , RTP

TCP vs. UDP

TCP

connection-oriented

confirmed service

high overhead

(header 20 bytes)

flow control

UDP

connectionless

unconfirmed service

low overhead

(header 8 bytes)

no flow control
